**Abstract.** We investigate the fully general class of non-expanding, non-twisting and shear-free \(D\)-dimensional geometries using the invariant form of geodesic deviation equation which describes the relative motion of free test particles. We show that the local effect of such gravitational fields on the particles basically consists of isotropic motion caused by the cosmological constant \(\Lambda\), Newtonian-type tidal deformations typical for spacetimes of algebraic type D or II, longitudinal motion characteristic for spacetimes of type III, and type N purely transverse effects of exact gravitational waves with \(D(D - 3)/2\) polarizations. We explicitly discuss the canonical forms of the geodesic deviation motion in all algebraically special subtypes of the Kundt family for which the optically privileged direction is a multiple Weyl aligned null direction (WAND), namely \(D(a), D(b), D(c), D(d), III(a), III(b), III, II, II(a), II(b), II(c)\) and \(II(d)\). We demonstrate that the key invariant quantities determining these algebraic types and subtypes also directly determine the specific local motion of test particles, and are thus measurable by gravitational detectors. As an example, we analyze an interesting class of type N or II gravitational waves which propagate on backgrounds of type O or D, including Minkowski, Bertotti–Robinson, Nariai and Plebański–Hacyan universes.

1. Introduction

Spacetimes of the Kundt class are defined by a purely geometric property, namely that they admit a geodesic null congruence which is non-expanding, non-twisting and shear-free. In the context of four-dimensional general relativity, such vacuum and pure radiation spacetimes of type N, III, or O were introduced and initially studied 50 years ago by Wolfgang Kundt [1, 2].

The whole Kundt class is, in fact, much wider. It admits a cosmological constant, electromagnetic field, other matter fields and supersymmetry. The solutions may be of various algebraic types and can be extended to any number $D$ of dimensions. All Kundt spacetimes (without assuming field equations) can be written as

$$ds^2 = g_{pq}(u, x) \, dx^p dx^q + 2 \, g_{ur}(r, u, x) \, du \, dx^p - 2 \, du \, dr + g_{uu}(r, u, x) \, du^2,$$  

(1)

see [1–9]. In this metric, the coordinate $r$ is an affine parameter along the optically privileged null congruence $k = \partial_r$ (with vanishing expansion, twist and shear), $u = \text{const.}$ label null (wave)surfaces, and $x \equiv (x^2, x^3, \ldots, x^{D-1})$ are $D-2$ spatial coordinates in the transverse Riemannian space. The spatial part $g_{pq}$ of the metric must be independent of $r$, all other metric components $g_{up}$ and $g_{uu}$ can be functions of all the coordinates $(r, u, x)$.

The Kundt class of spacetimes is one of the most important families of exact solutions in Einstein’s general relativity theory, see chapter 31 of the monograph [3] or chapter 18 of [4] for reviews of the standard $D = 4$ case. It contains several famous subclasses, both in four and higher number of dimensions, with interesting mathematical and physical properties. The best-known of these are pp-waves (see [3–6, 10–14] and references therein) which admit a covariantly constant null vector field. There are also VSI and CSI spacetimes [5, 6, 11–16] for which all polynomial scalar invariants constructed from the Riemann tensor and its derivatives vanish and are constant, respectively. Moreover, all the relativistic gyratons known so far [17–24], representing the fields of localised spinning sources that propagate with the speed of light, are also specific members of the Kundt class. Vacuum and conformally flat pure radiation Kundt spacetimes provide an exceptional case for the invariant classification of exact solutions [25–31], and all type D pure radiation solutions are also known [32, 33]. All vacuum Kundt solutions of type D were found and classified a long time ago [34] and generalized to electrovacuum and any value of the cosmological constant [35, 36]. These contain a subfamily of direct-product spacetimes, namely the Bertotti–Robinson, (anti-)Nariai and Plebański–Hacyan spacetimes of type O and D (see chapter 7 of [4], [23] and [24] for higher-dimensional generalizations) representing, for example, extreme limits and near-horizon geometries. With Minkowski and (anti-)de Sitter spaces they form the natural backgrounds for non-expanding gravitational waves of types N and II [37–44].

In our studies here we consider the fully general class of Kundt spacetimes of an arbitrary dimension $D \geq 4$ (results for the standard general relativity are obtained by simply setting $D = 4$). Taking the spacetime dimension as a free parameter $D$, we can investigate whether the extension of the Kundt family to $D > 4$ exhibits some qualitatively different features and unexpected properties. Our paper is thus also a contribution to the contemporary research analyzing various aspects of Einstein’s gravity extended to higher dimensions. Explicit Kundt solutions help us illustrate specific physical properties and general mathematical features of such theories.

Specifically, we systematically investigate the complete $D \geq 4$ Kundt class of solutions using geodesic deviation and discuss the corresponding effects on free test
particles. In section 2 we summarize the equation of geodesic deviation, introduce invariant amplitudes of the gravitational field, and we discuss them for the fully general Kundt family of geometries. In section 3 we derive expressions for these amplitudes, and in section 4 we evaluate them explicitly for all algebraically special Kundt spacetimes for which the optically privileged congruence is generated by a multiple WAND. The main results are presented in section 5 where we discuss the specific structure of relative motion of test particles for all possible algebraic types and subtypes of such Kundt geometries, see subsections 5.1–5.12. In the final section 6 we present a particular example, namely an interesting class of type II and N non-expanding gravitational waves on D and O backgrounds of any dimension.

2. Geodesic deviation in the fully general Kundt spacetime

Relative motion of nearby free test particles (without charge and spin) is described by the equation of geodesic deviation [45,46]. It has long been used as an important tool for studies of four-dimensional general relativity, in particular to analyze fields representing gravitational waves and black hole spacetimes (see [47–50] for more details and references). In our recent work [50] generalizing [41] we demonstrated that the equation of geodesic deviation in any $D$-dimensional spacetime can be expressed in the invariant form (using Einstein’s field equations $R_{ab} - \frac{1}{2} R g_{ab} + \Lambda g_{ab} = 8\pi T_{ab}$)

$$\ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} + \frac{1}{\sqrt{2}} \left( \Psi_{1T^i} - \Psi_{3T^i} \right) Z^{(j)} + \frac{8\pi}{D-2} \left[ T^{(i)(j)} Z^{(j)} (T_{(0)(0)} + \frac{2T}{D-1}) Z^{(1)} \right],$$

$$\ddot{Z}^{(j)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(j)} - \frac{1}{\sqrt{2}} \left( \Psi_{1T^j} - \Psi_{3T^j} \right) Z^{(i)} - \frac{8\pi}{D-2} \left[ T^{(j)(i)} Z^{(i)} (T_{(0)(0)} + \frac{2T}{D-1}) Z^{(1)} \right],$$

$$i, j = 2, \ldots, D - 1.$$ Here $Z^{(1)}, Z^{(2)}, \ldots, Z^{(D-1)}$ are spatial components $Z^{(i)} \equiv e^{(i)} \cdot Z$ of the separation vector $Z$ between the two test particles in a natural interpretation orthonormal frame $\{e_a\}$, $e_a \cdot e_b = \eta_{ab}$, where $e_{(0)} = u$ is the velocity vector of the fiducial test particle, and $\ddot{Z}^{(1)}, \ddot{Z}^{(2)}, \ldots, \ddot{Z}^{(D-1)}$ are the corresponding relative geodesic accelerations $\ddot{Z}^{(i)} \equiv e^{(i)} \cdot (D^2 Z / \sqrt{\tau^2})$. The coefficients $T_{ab} \equiv T(e_a, e_b)$ denote frame components of the energy-momentum tensor ($T$ is its trace), and the scalars

$$\Psi_{0^i} = C_{abcd} k^a m^b_l k^c m^d_l,$$

$$\Psi_{1T^i} = C_{abcd} k^a l^b k^c m^d_l,$$

$$\Psi_{2T^i} = C_{abcd} k^a l^b l^c k^d,$$

$$\Psi_{3T^i} = C_{abcd} l^a k^b l^c m^d_l,$$

$$\Psi_{4^i} = C_{abcd} l^a m^b_l l^c m^d_l,$$

with indices $i, j, k, l = 2, \ldots, D - 1$, are components of the Weyl tensor with respect to the null frame $\{k, l, m_i\}$ associated with $\{e_a\}$ via relations $k = \frac{1}{\sqrt{2}}(u + e_{(1)}), \ l = \frac{1}{\sqrt{2}}(u - e_{(1)}), \ m_i = e_{(i)}$, see figure 1.
Figure 1. Evolution of the separation vector $Z$ that connects particles moving along geodesics $\gamma(\tau)$, $\bar{\gamma}(\tau)$ is given by the equation of geodesic deviation (2) and (3). Its components are expressed in the orthonormal frame $\{e_a\}$ with $e_{(0)} = u$. The associated null frame $\{k, l, m\}$ is also indicated.

The Weyl tensor components (4) are listed by their boost weight and directly generalize the standard Newman–Penrose complex scalars $\Psi^A$ known from the $D = 4$ case [50, 51]. In equations (2), (3), only the “electric part” of the Weyl tensor with respect to $u$ represented by the scalars in the left column of (4) occurs. All these scalars exhibit the standard symmetries of the Weyl tensor, for example

\[ \Psi_{4:ij} = \Psi_{4(i)j}, \quad \Psi_{4:k} = 0, \quad \Psi_{3:ijk} = \Psi_{3[i]k]. \]

Moreover, there are relations between the left and right columns of (4), namely

\[ \Psi_{1T} = \Psi_{1k}, \quad \Psi_{3T} = \Psi_{3k}, \]
\[ \Psi_{2S} = \Psi_{2T}, \quad \Psi_{2T(i)} = \frac{1}{2} \Psi_{2(i)}, \quad \Psi_{2T(ij)} = \frac{1}{2} \Psi_{2ijkl}. \]

Finally, let us remark that our notation which uses the symbols $\Psi^A$... in any dimension is related to the notations employed elsewhere, namely in [5, 12], [52, 53], and [6, 54]. Identifications for the components present in the invariant form of the equation of geodesic deviation are summarized in table 1 (more details can be found in [50]).

Physical interpretation of Kundt spacetimes using geodesic deviation

For the most general Kundt spacetime (1), the null interpretation frame adapted to an arbitrary observer moving along the timelike geodesic \( \gamma(\tau) \), whose velocity vector is \( u = \dot{r} \partial_r + \dot{u} \partial_u + \dot{x}^p \partial_p \) (normalized as \( u \cdot u = -1 \), so that \( \ddot{u} \neq 0 \)), takes the form\[\]
\[k = \frac{1}{\sqrt{2}u} \partial_r,\]
\[l = (\sqrt{2} \dot{r} - \frac{1}{\sqrt{2}u}) \partial_r + \sqrt{2} \ddot{u} \partial_u + \sqrt{2} \dot{x}^p \partial_p,\]
\[m_i = \frac{1}{u} m_i^p (g_{pu} \ddot{u} + g_{pq} \dot{x}^q) \partial_r + m_i^p \partial_p,\]
where \( m_i^p \) satisfy \( g_{pq} m_i^p m_j^q = \delta_{ij} \) to fulfill the normalization conditions \( m_i \cdot m_j = \delta_{ij} \), \( k \cdot l = -1 \). Notice that the vector \( k \) is oriented along the non-expanding, non-twisting and shear-free null congruence \( k = \partial_r \) defining the Kundt family. Moreover, \( u = \frac{1}{\sqrt{2}} (k + l) \) and \( e_{(1)} = \frac{1}{\sqrt{2}} (k - l) = \sqrt{2}k - u \). The spatial vector \( e_{(1)} \) is thus uniquely determined by the optically privileged null congruence of the Kundt family and the observer’s velocity \( u \). For this reason we call such a special direction \( e_{(1)} \) longitudinal, while we refer to the \( D - 2 \) directions \( e_{(i)} = m_i \) are transverse.

To evaluate the scalars (4) we have to project coordinate components of the Weyl tensor \( C_{abcd} \) of the generic Kundt spacetime, which can be found in appendix A of [9], onto the interpretation frame (7). Since \( C_{rprq} = 0 \), we immediately obtain \( \Psi_{ij} = 0 \), while the remaining Weyl scalars are in general non-zero. The relative motion of free test particles in any \( D \)-dimensional Kundt spacetime (1), determined by the equation of geodesic deviation (2), (3), can thus be naturally decomposed into the following components:

- The presence of the cosmological constant \( \Lambda \) is encoded in the term

The scalars $\Psi_{ij}$, characteristic for type N spacetimes, can be interpreted as amplitudes of transverse gravitational waves propagating along the spatial direction $+e_{(1)}$. These components of the field influence test particles as

$$\begin{pmatrix} \dot{Z}^{(1)} \\ \dot{Z}^{(i)} \end{pmatrix} = -\frac{1}{2} \begin{pmatrix} 0 & 0 \\ 0 & \Psi_{ij} \end{pmatrix} \begin{pmatrix} Z^{(1)} \\ Z^{(j)} \end{pmatrix}. \hspace{1cm} (11)$$

They obviously cause purely transverse effects because there is no acceleration in the privileged longitudinal direction $e_{(1)}$. The scalars $\Psi_{ij}$ form a symmetric traceless matrix of dimension $(D-2) \times (D-2)$, see (5). This matrix describing the amplitudes of gravitational waves has $\frac{1}{2}D(D-3)$ independent components corresponding to distinct polarization modes.

More details about these general effects of any gravitational field on test particles can be found in [50]. Their explicit discussion in the context of Kundt spacetimes will be presented in subsequent sections of this contribution.

There are also specific direct effects of matter in the equation of geodesic deviation (2), (3) which are determined by the frame components of the corresponding energy-momentum tensor $T_{ab}$. As an explicit illustration, we present here two physically interesting examples:

- For pure radiation (or "null dust") aligned along the null direction $k$, the energy-momentum tensor is $T_{ab} = \rho k_a k_b$ where $\rho$ represents radiation density. Its trace vanishes, $T = 0$, and the only nonvanishing components of $T_{ab}$ in the equation of geodesic deviation (2), (3) reduce to

$$\begin{pmatrix} \dot{Z}^{(1)} \\ \dot{Z}^{(i)} \end{pmatrix} = -\frac{4\pi \rho}{D-2} \begin{pmatrix} 0 & 0 \\ 0 & \delta_{ij} \end{pmatrix} \begin{pmatrix} Z^{(1)} \\ Z^{(j)} \end{pmatrix}. \hspace{1cm} (12)$$

There is no acceleration in the longitudinal spatial direction $e_{(1)}$ and the effect in the transverse space is isotropic. Moreover, since $\rho > 0$, it causes a radial contraction which may eventually lead to exact focusing.

- For an electromagnetic field aligned with the Kundt geometry (i.e., $F_{ab} k^b = E_k a$ where $k = \partial_t$) the most general form of the Maxwell tensor is

$$F = E \, dr \wedge du + \sigma_p \, du \wedge dx^p + \frac{1}{2} B_{pq} \, dx^p \wedge dx^q. \hspace{1cm} (13)$$

Evaluating the energy-momentum tensor $T_{ab} = \frac{1}{\pi} (F_{ac} F_b^c - \frac{1}{2} g_{ab} F_{cd} F^{cd})$ in the interpretation orthonormal frame, the corresponding effects on (uncharged) test particles, as given by the equation of geodesic deviation, take the form

$$\begin{pmatrix} \dot{Z}^{(1)} \\ \dot{Z}^{(i)} \end{pmatrix} = \begin{pmatrix} T & T_i \\ T_j & T_{ij} \end{pmatrix} \begin{pmatrix} Z^{(1)} \\ Z^{(j)} \end{pmatrix}, \hspace{1cm} (14)$$

where

$$T = -\frac{2}{D-2} \left[ (E^2 + B^2) + \frac{D-4}{D-1} (E^2 - B^2) \right],$$

$$T_i = -\frac{2}{D-2} m_i \dot{E} \left[ \dot{E} (E^2 g_{pq} + B^2 p^q) + \ddot{u} (E E_p - B_{pq} E_m g^{qm}) \right], \hspace{1cm} (15)$$

$$T_{ij} = \frac{2}{D-2} \left[ m_i m_j B_{pq}^2 - \delta_{ij} \left( B^2 + \frac{D-4}{D-1} (E^2 - B^2) + \dot{E}^2 (E^2 g_{pq} + B^2 p^q) + 2 \ddot{u} (E E_p - B_{pq} E_m g^{qm}) + \dot{u}^2 E_p g^{pq} \right) \right].$$
with convenient auxiliary variables defined as
\[ \mathcal{E}_p \equiv \mathcal{E}_{up} = \sigma_p, \quad B^2_{pq} \equiv B_{pn}B_{qm}g^{mn}, \quad B^2 \equiv \frac{1}{2}B_{pm}B_{qn}g^{pq}g^{mn}. \]  
(16)

The motion simplifies considerably if the magnetic field is absent \((B_{pq} = 0)\):
\[ T = -\frac{2}{D} \frac{D-5}{D-1} \mathcal{E}^2, \]
\[ T_i = -\frac{D}{D-2} m_i^p \left( g_{pq} \dot{x}^q \mathcal{E}^2 + \dot{u} \mathcal{E}_p \right), \]
\[ T_{ij} = -\frac{D}{D-2} \delta_{ij} \left( \frac{D-4}{D-1} \mathcal{E}^2 + g_{pq} \dot{x}^p \dot{x}^q \mathcal{E}^2 + 2 \dot{u} \dot{x}^p \mathcal{E}_p + \dot{u}^2 \mathcal{E}_p \mathcal{E}_q g^{pq} \right), \]
in particular when \(D = 4\) and \(\sigma_p = 0\) (in which case \(\mathcal{E}_p = \mathcal{E}_{g_{up}}\)).

3. Explicit evaluation of the Weyl scalars \(\Psi_A\)

The invariant amplitudes \(\Psi_A\) of various gravitational field components (9)–(11) combine the local curvature of the Kundt spacetime with the kinematics of specific motion along an arbitrary timelike geodesic \(\gamma(\tau)\). These should be evaluated at any given event corresponding to the actual position of the observer along \(\gamma(\tau)\), with its actual velocity \(u = \dot{r} \partial_r + \dot{\partial}_a + \dot{x}^p \partial_p\).

The scalars \(\Psi_{2S}, \Psi_{2Ti}, \Psi_{1Ti}, \Psi_{3Ti}, \Psi_{4Ti}\) (and \(\Psi_{0Ti} = 0\)) which enter the geodesic deviation equation (2), (3) can most conveniently be expressed explicitly if we employ the relation between the interpretation null frame (7) (adapted to the chosen geodesic observer) and the natural null frame for the Kundt geometry (1) which is
\[ k^\text{nat} = \partial_r, \]
\[ l^\text{nat} = \frac{1}{2} g_{au} \partial_a + \partial_u, \]
\[ m_i^\text{nat} = m_i^p \left( g_{up} \partial_r + \partial_p \right). \]
(18)

The transition between the null frames (18) and (7) is a Lorentz transformation associated with the choice of different (timelike) observers, as explained in more detail in section V and appendix C of our work [50]. Specifically, the general interpretation frame is obtained from the natural one by combining a boost followed by a null rotation with fixed \(k^\text{nat}\) (see equations (C3) and (C1) of [50]),
\[ k = Bk^\text{nat}, \]
\[ l = B^{-1}l^\text{nat} + \sqrt{2} L^i m_i^\text{nat} + |L|^2 Bk^\text{nat}, \]
\[ m_i = m_i^\text{nat} + \sqrt{2} L_i Bk^\text{nat}, \]
(19)

where \(|L|^2 \equiv \delta^{ij} L_i L_j\) and
\[ B = \frac{1}{\sqrt{2} u}, \quad L_i = g_{pq} m_i^p \dot{x}^q. \]
(20)

Conversely, the natural frame (18) is obtained from the interpretation frame (7) as a particular case when \(\sqrt{2} \dot{u} = 1, \dot{x}^p = 0\) (and thus \(\sqrt{2} \dot{r} - 1 = \frac{1}{2} g_{au}\) due to the assumed normalization \(u \cdot u = -1\)), i.e., \(B = 1, L_i = 0\). This corresponds to special observers with no motion in the transverse spatial directions (\(\dot{x}^p = 0\) for all \(p = 2, \ldots, D-1\)).

Under the Lorentz transformation (19), the Weyl scalars change as
\[ \Psi_{0Ti} = 0, \quad \Psi_{1Ti} = B \Psi_{1Ti}^\text{nat}, \quad \Psi_{1ijk} = B \Psi_{1ijk}^\text{nat}, \]
\[ \Psi_{2S} = \Psi_{2S}^\text{nat} - 2 \sqrt{2} \Psi_{1Ti}^\text{nat} B L^i, \]
\[ \Psi_{2Tij} = B \Psi_{2Tij}^\text{nat} - \sqrt{2} \Psi_{1Ti}^\text{nat} B L^i. \]
where we obtained the following surprisingly simple expressions, namely

\[ D \text{general Kundt spacetime of algebraic type II} \]

Kundt geometry represented by the metric (1) is (at least) of algebraic type I can be written in the form (1) with \( g_{ij} = \delta_{ij} \). For such algebraically special Kundt geometries (22) with the multiple WAND, there is \( \Psi_{nat}^{2T(ij)} \). Moreover, in [9] we demonstrated that explicitly

\[ \Psi_{nat}^{2T(ij)} = \Psi_{nat}^{2T(ij)} \]

represent the components (4) of the Weyl tensor in the natural null frame (18). Recall that the coordinate components of \( C_{abcd} \) were presented in appendix A of [9]. These scalars can also be used purely locally. For some purposes, it is not necessary to evaluate all the functions along \( \gamma(\tau) \) and express them in terms of the proper time \( \tau \) of the geodesic observer. For example, to determine the algebraic type of the spacetime at any given event, we only need to consider the values of the constants \( \Psi_{A}^{nat} \) and their mutual relations. Moreover, they directly determine the actual acceleration of test particles in various spatial directions.

4. Algebraically special Kundt spacetimes

In our recent work [9], we analyzed the geometric and algebraic properties of all Kundt spacetimes for which the optically privileged (non-expanding, non-twisting, shear-free) congruence is generated by the null vector field \( \mathbf{k} = \partial_{\tau} \) that is a multiple WAND (Weyl aligned null direction).

Specifically, \( \Psi_{nat}^{ij} = 0 \) immediately confirms the results of [6, 7, 55] that a generic Kundt geometry represented by the metric (1) is (at least) of algebraic type I (subtype I(b), in fact) and \( \mathbf{k} = \mathbf{k}_{nat} \) is WAND. In [9] we also demonstrated that the general Kundt spacetime of algebraic type II with respect to the double WAND \( \mathbf{k} \) in any dimension \( D \) can be written in the form (1) with \( g_{\mu\nu} = e_{\mu} + f_{\mu} r \) (at most) linear in \( r \),

\[ ds^2 = g_{pq} dx^p dx^q + 2(e_p + f_p r) du dx^p - 2 du dr + g_{uu}(r, u, x) du^2, \]  
(22)

where \( g_{pq}(u, x) \), \( e_p(u, x) \), \( f_p(u, x) \), \( p = 2, \ldots, D - 1 \), are functions independent of \( r \).

For such algebraically special Kundt geometries (22) with the multiple WAND \( \mathbf{k} = \mathbf{k}_{nat} \) there is \( \Psi_{nat}^{D} = 0 = \Psi_{nat}^{1T(ij)} \). Moreover, in [9] we explicitly evaluated all the remaining Weyl scalars \( \Psi_{A}^{nat} \) of the boost weights 0, -1, -2. After lengthy calculations, we obtained the following surprisingly simple expressions, namely

\[ \Psi_{nat}^{2T} = D - 3 \left[ \frac{1}{2} g_{uu,rr} + \frac{1}{D - 2} \left( \frac{sR}{D - 3} + f \right) \right], \]  
(23)

\[ \Psi_{nat}^{2T(ij)} = \Psi_{nat}^{2T(ij)} + \frac{1}{D - 2} \delta_{ij} \Psi_{nat}^{2S}, \]  
(24)

\[ \tilde{\Psi}_{nat}^{2T(ij)} = \frac{m_p^2 m_q^2}{D - 2} \left[ \left( \frac{sR_{pq}}{D - 2} g_{pq} sR + \frac{1}{2} (D - 4) \left( f_{pq} - \frac{1}{D - 2} g_{pq} f \right) \right) \right], \]  
(25)
\[\psi_{2\,ijkl}^{nat} = \tilde{\psi}_{2\,ijkl}^{nat} - \frac{2}{(D-3)(D-4)} (\delta_{ik} \delta_{jl} - \delta_{il} \delta_{jk}) \psi_{2\,kl}^{nat}\]
+ \frac{2}{D-4} (\delta_{jk} \psi_{2\,T(i)l}^{nat} - \delta_{il} \psi_{2\,T(j)k}^{nat} + \delta_{jl} \psi_{2\,T(i)k}^{nat} + \delta_{ik} \psi_{2\,T(j)l}^{nat}), \tag{26}\]
\[\tilde{\psi}_{2\,ijkl}^{nat} = m_i^pm_j^pm_k^qS_{cmpq}, \tag{27}\]
\[\psi_{2\,ij}^{nat} = 2 \psi_{2\,T(i)j}^{nat} = m_i^pm_j^q F_{pq}, \tag{28}\]
\[\psi_{3\,ij}^{nat} = -m_i^p D - \frac{3}{2} \left[ \frac{1}{2} (r f_p g_{uu,rr} + g_{uu,rp} - f_p,u_p) + e_p \left( \frac{1}{2} g_{uu,rr} - \frac{1}{4} f^q f_q \right)\right. \]
+ \frac{1}{4} f^q e_q f_p - \frac{1}{2} f^q F_{qp} - \frac{1}{D-3} X_p - r \left( \frac{1}{2} f^q F_{qp} + \frac{1}{D-3} Y_p \right), \tag{29}\]
\[\psi_{3\,ij}^{nat} = \psi_{3\,jk}^{nat} + \frac{1}{D-3} (\delta_{ij} \psi_{3\,Tk}^{nat} - \delta_{ik} \psi_{3\,Tj}^{nat}), \tag{30}\]
\[\tilde{\psi}_{3\,ij}^{nat} = m_i^pm_j^pm_k^q \left[ \left( X_{pmq} - \frac{2}{D-3} g_{p[m} X_{q]} \right) + r \left( Y_{pmq} - \frac{2}{D-3} g_{p[m} Y_{q]} \right) \right], \tag{31}\]
\[\psi_{q\,ij}^{nat} = m_i^q m_j^q \left( W_{pq} - \frac{1}{D-2} g_{pq} W \right), \tag{32}\]
in which \( g_{pq} m_i^p m_j^q = \delta_{ij}, \)
\[X_{pmq} \equiv e_{[q|m]|p} + F_{qm} e_p + F_{p[m} e_q + e_{p[m} f_q - f_{p[m} e_q] + g_{p[m,u]|q}; \tag{33}\]
\[Y_{pmq} \equiv f_{[q|m]|p} + F_{qm} f_p + F_{p[m} f_q]; \tag{34}\]
\[W_{pq} \equiv \frac{1}{2} (g_{uu})_{[p|q]} + \frac{1}{2} g_{uu} f_{[p|q]} + \frac{1}{2} g_{uu, (p)f_q} \]
+ \frac{1}{2} g_{uu,r} (r f_{[p|q]} + e_{pq}) - \frac{1}{2} g_{uu,rr} (r^2 f_{p} f_{q} + 2 f_{p} f_{(q) e}) + e_{p} e_{q} \]
+ \frac{1}{2} \left[ (f_{[p,u} - g_{uu,rp})(r f_{p} + e_{p}) + (f_{q,u} - g_{uu,qr})(r f_{q} + e_{q}) \right. \]
+ r^2 g^{mn} F_{mp} F_{nq} + r (f_{[p,u]} - g_{uu,rq})(r f_{p} + e_{p}) \]
+ e_{p} e_{q} + \frac{1}{2} g_{pq,uu} + g^{mn} E_{mp} E_{nq} + f^{mn} E_{mp} e_{q} - e^{mn} E_{mp} f_{q} \]
+ \frac{1}{2} (e^{mn} f_{[p|q]} + f^{mn} e_{m} f_{[q|p]} - \frac{1}{2} f^{mn} e_{m} f_{[q|p]}), \tag{35}\]
and their contractions are
\[X_q \equiv g^{pm} X_{pmq}, \quad Y_q \equiv g^{pm} Y_{pmq}, \quad W \equiv g^{pq} W_{pq}. \tag{36}\]
Note that \( W_{pq} = W_{qp}, \) while \( X_{pqm} = -X_{pqr} \) and \( Y_{pqm} = -Y_{pqr}, \) so that \( X_q \) and \( Y_q \) are the only non-trivial contractions of \( X_{pqm} \) and \( Y_{pqm}, \) respectively.

In these expressions we have introduced convenient geometric quantities
\[f^p \equiv g^{pq} f_{q}, \tag{37}\]
\[f_{p|q} \equiv f_{p,q} - \Gamma_{pq} f_{m}, \tag{38}\]
\[f^p|_p \equiv g^{pq} f_{p|q}, \tag{39}\]
\[f_{pq} \equiv f_{p|q} + \frac{1}{2} f_{p} f_{q}, \tag{40}\]
\[f \equiv g^{pq} f_{pq} = f^p|_p + \frac{1}{2} f^p f_{p}, \tag{41}\]
\[F_{pq} \equiv f_{[p|q]} - f_{[q|p]}, \tag{42}\]
\[f_{m|[q|p]} \equiv f_{[m|q,p} - \Gamma_{pm} f_{[n|q]} - \Gamma_{pq} f_{[m|n]}, \tag{43}\]
\[f_{p,u|q} \equiv (f_{p,u})_{[q]} - f_{p,u} - f_{n,u} \Gamma_{pq} \tag{44}\]
\[f_{(p,u)|q} \equiv f_{(p,q),u} - f_{n,u} \Gamma_{pq}, \tag{45}\]
\[e^p \equiv g^{pq} e_{q}. \tag{46}\]
Physical interpretation of Kundt spacetimes using geodesic deviation

\[ e_{p|q} \equiv e_{p,q} - \Gamma^m_{pq} e_m, \]  
\[ e_{pq} \equiv e_{(p|q)} - \frac{1}{2} g_{pq}, \]  
\[ E_{pq} \equiv e_{[p|q]} + \frac{1}{2} g_{pq}, \]  
\[ e_{[m|q]} \equiv e_{(m|q)} - \Gamma^p_{mn} e_n - \Gamma^n_{pq} e_{mn}, \]  
\[ e_{p,u}|q| \equiv e_{p,u|q} = e_{p,u} - e_{n,u} \Gamma^n_{pq}, \]  
\[ g_{p(m,u)|q} \equiv g_{p(m,u)|q} + \frac{1}{2} \left( \Gamma^m_{pn} g_{pq,u} - \Gamma^n_{pq} g_{pm,u} \right), \]  
\[ (g_{uu})|q| \equiv g_{uu,pq} - g_{uu,n} \Gamma^n_{pq}, \]  
\[ \Delta g_{uu} \equiv \delta_{pq} (g_{uu})|q|. \]

The symbol || indicates covariant derivative with respect to the spatial metric \( g_{pq} \) in the transverse \( (D-2) \)-dimensional Riemannian space. The corresponding Riemann and Ricci tensors are \( S R_{mpnq} \) and \( S R_{pq} \), the Ricci scalar is \( S R \) and the Weyl tensor reads \( S C_{mpnq} \). All the quantities \( (37) - (53) \) are independent of the coordinate \( r \).

The explicit Weyl scalars (23)–(32) in the natural frame (18) enabled us in [9] to determine, without assuming any field equations, the classification scheme of all algebraic types and subtypes with respect to the multiple WAND \( k = \partial_r \). A summary of such Kundt geometries (22) in any dimension \( D \) is presented in table 3.

Table 3. The classification scheme of algebraically special Kundt geometries (22) in any dimension \( D \) with \( k = k^{uut} = \partial_r \) being a multiple WAND. For type D subclass, the vector \( \Gamma^m = \frac{1}{4} g_{uu} \partial_r + \partial_u \) is a double WAND. If all conditions for type D are satisfied and conditions for the subtypes \( \Pi(a), \Pi(d), \Pi(c), \Pi(d) \) are also valid, we obtain the subtypes \( D(a), D(b), D(c), D(d) \), respectively. The subtype \( D(abcd) \) is equivalent to type O. In the classic \( D = 4 \) case, conditions for \( \Pi(b), \Pi(c) \) and \( \Pi(d) \) are always satisfied.

\[ e_{[m|q]} \equiv e_{(m|q)} - \Gamma^p_{mn} e_n - \Gamma^n_{pq} e_{mn}, \]  
\[ e_{p,u}|q| \equiv e_{p,u|q} = e_{p,u} - e_{n,u} \Gamma^n_{pq}, \]  
\[ g_{p(m,u)|q} \equiv g_{p(m,u)|q} + \frac{1}{2} \left( \Gamma^m_{pn} g_{pq,u} - \Gamma^n_{pq} g_{pm,u} \right), \]  
\[ (g_{uu})|q| \equiv g_{uu,pq} - g_{uu,n} \Gamma^n_{pq}, \]  
\[ \Delta g_{uu} \equiv \delta_{pq} (g_{uu})|q|. \]
5. Geodesic deviation in Kundt spacetimes with a multiple WAND k

In the remaining parts of this paper we will discuss an important family of algebraically special Kundt spacetimes (22). As described in the previous section, Weyl scalars of the two highest boost weights vanish identically, \( \Psi_{0^i} = 0 \), \( \Psi_{1T^i} = 0 = \Psi_{10^i} \). From (21) we then immediately obtain

\[
\Psi_{0^i} = 0, \quad \Psi_{1T^i} = 0, \quad \Psi_{10^i} = 0. \tag{56}
\]

The geodesic deviation equations (2), (3) (omitting the frame components of \( T_{ab} \)) encoding the direct influence of matter, for example (12) or (14)) for the case of the Kundt class of (vacuum) spacetimes (22) thus reduce to

\[
\ddot{Z}^{(1)} = \frac{2\Lambda}{(D - 2)(D - 1)} Z^{(1)} + \Psi_{2S} Z^{(1)} - \frac{1}{\sqrt{2}} \Psi_{3T^i} Z^{(i)}, \tag{57}
\]

\[
\ddot{Z}^{(i)} = \frac{2\Lambda}{(D - 2)(D - 1)} Z^{(i)} - \Psi_{2T^{(i)}} Z^{(j)} - \frac{1}{\sqrt{2}} \Psi_{3T^i} Z^{(1)} - \frac{1}{2} \Psi_{4^i} Z^{(j)}. \tag{58}
\]

The corresponding Weyl scalars in the interpretation null frame are given by expressions (21) with (20), which now simplify considerably due to (56):

\[
\Psi_{2S} = \Psi_{2S}^{\text{nat}}, \quad \Psi_{2T^{(i)}} = \Psi_{2T^{(i)}}^{\text{nat}},
\]

\[
\Psi_{3T^i} = \sqrt{\frac{2}{3}} u \Psi_{3T^i}^{\text{nat}} + \sqrt{\frac{2}{5}} \dot{Z} p q \left( (\Psi_{2^i}^{\text{nat}} - \Psi_{2T^{(i)}}^{\text{nat}}) m^q - \Psi_{2S}^{\text{nat}} m^q \right),
\]

\[
\Psi_{4^i} = 2 \dot{u}^2 \Psi_{4^i}^{\text{nat}} + 4 \dot{u} \dot{Z} p q \left( \Psi_{3T^i}^{\text{nat}} m^q - \Psi_{3T^{(i)}}^{\text{nat}} m^q \right)
+ 2 \dot{Z} p q \left( g_{pq} \Psi_{2T^{(i)}}^{\text{nat}} - g_{pm} g_{qn} \Psi_{2S}^{\text{nat}} m^m m^n + g_{pm} g_{qn} \Psi_{2T^{(i)}}^{\text{nat}} m^m m^n - 2 g_{pm} g_{qn} \left( \Psi_{2T^i}^{\text{nat}} + \Psi_{2T^{(i)}}^{\text{nat}} \right) m^m m^n \right),
\]

where \( m^q \equiv \delta^q_i m^i \) and both the frame indices \( i, j, k, l \) and the coordinate indices \( p, q, m, n \) take the ranges \( 2, 3, \ldots, D - 1 \). The coefficients \( \Psi_{X}^{\text{nat}} \) are explicitly given by expressions (23)--(32). Notice that in (59), not only the "electric part" but also the "magnetic part" of the Weyl tensor with respect to \( u^{\text{nat}} \) occur due to the relative velocity \( \dot{u} \) between \( u \) and \( u^{\text{nat}} = \frac{1}{\sqrt{2}} (k^{\text{nat}} + p^{\text{nat}}) \). For completeness, the remaining "magnetic" Weyl tensor components in the interpretation frame that do not enter directly the equations of geodesic deviation (57), (58) are

\[
\Psi_{2^i} = \Psi_{2^i}^{\text{nat}}, \quad \Psi_{2^i^{(j)}} = \Psi_{2^i^{(j)}}^{\text{nat}},
\]

\[
\Psi_{3^i^{(k)}} = \sqrt{\frac{2}{3}} u \Psi_{3^i^{(k)}}^{\text{nat}} + \sqrt{\frac{2}{5}} \dot{Z} p q \left( \Psi_{2^i^{(k)}}^{\text{nat}} m^q - \Psi_{2T^{(k)}}^{\text{nat}} m^q + 2 m^q \Psi_{4^{(i)}}^{\text{nat}} \right). \tag{60}
\]

The specific relative motion of free test particles in any algebraically special Kundt spacetime (22) with a multiple WAND k thus consists of isotropic influence \( \Lambda \), Newtonian-like tidal deformations represented by \( \Psi_{2S} \), \( \Psi_{2T^{(i)}} \), longitudinal accelerations associated with the direction \( +e^{(1)} \) given by \( \Psi_{3T^i} \), and by transverse gravitational waves propagating along \( +e^{(1)} \) encoded in the symmetric traceless matrix \( \Psi_{4^i} \). These components were described separately in (8)--(11). The invariant amplitudes (59) combine the curvature of the Kundt spacetime with the kinematics of the specific geodesic motion. In contrast to longitudinal and transverse effects, the Newtonian-like deformations caused by \( \Psi_{2S} \) and \( \Psi_{2T^{(i)}} \) are independent of the observer’s velocity components \( \dot{u}^p \) and \( \dot{u} \).

We will now describe systematically the canonical structure of the relative motion of free test particles in all possible algebraic types and subtypes of the Kundt family summarized in table 3.
5.1. Type O Kundt spacetimes

For type O Kundt spacetimes, the Weyl tensor vanishes identically, so that all the Weyl scalars $\Psi_{\alpha}^{\mu\nu}$ given by (23)–(32) are zero. In view of (59), the geodesic deviation equations (57), (58) for the type O vacuum Kundt spacetimes reduce to

$$
\dot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)}, \quad \ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} \dddot{Z}^{(i)}.
$$

There is thus no distinction between the (generically privileged) longitudinal spatial direction $e^{(1)}(p)$ and the transverse spatial directions $e^{(i)}(p)$, $i = 2, \ldots, D - 1$. The relative motion is *isotropic* and fully determined by the cosmological constant $\Lambda$, see (8). This is in full agreement with the well-known fact [3, 4] that the only type O vacuum spaces are just Minkowski space, de Sitter space or anti-de Sitter space.

As shown in [9], for type O Kundt spacetimes (22) (with quadruple WAND $k = \partial_{k}$) the only non-trivial Weyl scalars are $\Psi_{\alpha}^{\mu\nu}$, the components (12) have to be superposed, and the equations of geodesic deviation become

$$
\dot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)}, \quad \ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} \dddot{Z}^{(i)} - \frac{4\pi \rho}{D-2} Z^{(i)}. \tag{62}
$$

Since $\rho > 0$, there is now an additional radial contraction in the transverse subspace.

For aligned electromagnetic field, the additional matter terms are given by (14).

5.2. Type N Kundt spacetimes

As shown in [9], for type N Kundt spacetimes (22) (with quadruple WAND $k = \partial_{k}$) the only non-trivial Weyl scalars are $\Psi_{\alpha}^{\mu\nu}$. Considering (59), the geodesic deviation equations (57), (58) for vacuum type N spacetimes thus take the form

$$
\dot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)}, \quad \ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} \dddot{Z}^{(i)}, \tag{63}
$$

where, due to (32),

$$
\Psi_{\alpha}^{\nu\mu} = m_{i} m_{q} (W_{pq} - \frac{1}{D-2} g_{pq} W) \tag{65}
$$

is a *symmetric and traceless matrix* fully determined by $W_{pq}$. The symmetric matrix $W_{pq}$ introduced in (35) simplifies, using all relevant conditions in table 3 (cf. [9]), to

$$
W_{pq} \equiv r \left[ \frac{1}{4} a g_{pq,u} + U_{(p|q)} + U_{(p|f)q} \right] - \frac{1}{4} \left[ (c_{p} - c_{f}p) \right]_{|q} + \left( c_{q} - c_{f}q \right)_{|p} - \frac{1}{2} \epsilon_{pq} + \left( a - \frac{1}{4} f^{m} f_{m} \right) \epsilon_{pq} + Z_{(pq)}, \tag{66}
$$

in which

$$
U_{p} \equiv \frac{1}{2} f_{p,u} - \frac{1}{4} f^{q} f_{q} e_{p} + \frac{1}{4} f^{q} e_{q} f_{p} - \frac{1}{2} f^{q} E_{qp} - \frac{1}{D-3} X_{p}, \tag{67}
$$

$$
Z_{pq} \equiv \frac{1}{2} c^{m} e_{m} f_{p} f_{q} + e_{p,u|q} - \frac{1}{2} g_{pq,u} - c^{m} E_{mp} f_{q} + g^{mn} E_{mp} E_{nq} - \frac{1}{D-3} X_{p} \epsilon_{pq}, \tag{68}
$$

and its trace is $W = g^{pq} W_{pq}$. The matrix $\Psi_{\alpha}^{\nu\mu}$ represents the *amplitudes of Kundt gravitational waves* in any dimension $D$. In general, their effect is superposed on the isotropic influence of the cosmological constant $\Lambda$, as given by (61). In the case $D = 4$ this has been analyzed and described in our previous work [41].
Physical interpretation of Kundt spacetimes using geodesic deviation

Figure 2. Deformation of a sphere of test particles in the case when two eigenvalues of $-\Psi_{\text{nat}}^{4 ij}$ are positive and one is negative ($D = 5$), the wave propagates in the direction $e_{(3)}$, and the transverse 3-space shown is spanned by $e_{(2)}, e_{(3)}, e_{(4)}$. Plot (a) is a global view, (b), (c), (d) are views from the top, front, right, respectively.

Since the set of $(D - 2) \times (D - 2)$ scalars $\Psi_{\text{nat}}^{4 ij}$ forms a symmetric and traceless matrix, it has in general $N \equiv \frac{1}{2}D(D - 3)$ independent components corresponding to the polarization modes of the gravitational wave. The remaining freedom in the choice of the transverse vectors $m_i$ of the interpretation frame (7) is given by the spatial rotations $m_i' = \Phi_{ij} m_j$, where $\Phi_{ij} \Phi_{kl} \delta_{jl} = \delta_{ik}$, which leave the null frame vectors $k, l$ unchanged. These rotations belong to the SO($D - 2$) group with $N_{\text{rot}} \equiv \frac{1}{2}(D - 2)(D - 3)$ independent generators. Therefore, the number of physical degrees of freedom is

$$N - N_{\text{rot}} = D - 3.$$  \hspace{1cm} (69)

This is exactly the number of independent eigenvalues of the matrix $\Psi_{\text{nat}}^{4 ij}$ which fully characterize the geodesic deviation deformation of a set of test particles. The sum of all these eigenvalues must vanish (the traceless property), so that there is at least one positive and one negative eigenvalue. The number of distinct options of dividing the remaining eigenvalues into three groups with positive, null and negative signs is $\binom{D - 2}{2}$.

Concerning the signs of the eigenvalues, we can thus distinguish $\frac{1}{2}(D - 2)(D - 3)$ geometrically and physically distinct cases.

Diagonalizing $-\Psi_{\text{nat}}^{4 ij}$ and denoting its eigenvalues as $A_2, A_3, \ldots$, we obtain

$$-\Psi_{\text{nat}}^{4 ij} = \text{diag}(A_2, A_3, \ldots, A_{D-1}) \quad \text{where} \quad \sum_{i=2}^{D-1} A_i = 0.$$  \hspace{1cm} (70)

In view of (64), the relative motion of (initially static) test particles is such that they recede in spatial directions with positive eigenvalues $A_i > 0$, while they converge with negative eigenvalues $A_i < 0$. In the directions where $A_i = 0$ the particles stay fixed.
Physical interpretation of Kundt spacetimes using geodesic deviation

Figure 3. Deformation of a sphere of test particles in the case when one eigenvalue of $-\Psi_{\text{nat}}^{4ij}$ is positive and two are negative.

In the classic $D = 4$ case, there is just one possibility, namely $A_3 = -A_2$, and the diagonalized matrix of the gravitational wave amplitudes takes the form

$$-\Psi_{\text{nat}}^{4ij} = \begin{pmatrix} A_2 & 0 \\ 0 & -A_2 \end{pmatrix}.$$  \hfill (71)

In the transverse 2-dimensional space perpendicular to the privileged propagation direction $e_{(1)}$, we observe the standard gravitational wave effect, in which the set of test particles expands in the direction $e_{(2)}$ when $A_2 > 0$ and simultaneously contracts by the same amount in the perpendicular direction $e_{(3)}$ (or vice versa if $A_2 < 0$), unless one has the trivial case $A_2 = 0$.

In higher dimensions, many more possibilities and new observable effects arise. For example, in the first non-trivial case $D = 5$, the corresponding transverse space spanned by $(e_{(2)}, e_{(3)}, e_{(4)})$ is 3-dimensional. Concerning the deformation of a 3-dimensional test sphere in this space, there are three physically distinct situations determined by $A_2, A_3, A_4$, namely:

- two eigenvalues are positive and one is negative, see figure 2(a),
- one eigenvalue is positive and two are negative, see figure 3(a),
- one eigenvalue is positive, one is zero and one is negative, see figure 4(a).

From the point of view of a gravitational wave detector located in our (1+3)-dimensional “real” universe locally spanned by the vectors $(\mathbf{u}, e_{(1)}, e_{(2)}, e_{(3)})$ where $e_{(1)}$ is the propagation direction, $(e_{(2)}, e_{(3)})$ defines the plane of the detector, while $e_{(4)}$ is the extra (directly unobservable) dimension, we would see the following “peculiar” effects in which the usual traceless property in $(e_{(2)}, e_{(3)})$ is violated:
Figure 4. Deformation of a sphere of test particles in the case when one eigenvalue of $-\Psi_{4ij}^{\text{nat}}$ is positive, one is zero and one is negative.

- both $A_2, A_3 \neq 0$ (either positive or negative), $A_4 = -(A_2 + A_3)$ due to (70):

$$-\Psi_{4ij}^{\text{nat}} = \begin{pmatrix} A_2 & 0 & 0 & 0 \\ 0 & A_3 & 0 & 0 \\ 0 & 0 & -(A_2 + A_3) & 0 \end{pmatrix}.$$  

In the directly observable first sector of dimension $2 \times 2$, the eigenvalues $A_2$ and $A_3$ can have arbitrary values now. Thus, the ring of test particles in these two directions (a section through the 3-sphere in the transverse space) may

- recede in both directions $e_{(2)}, e_{(3)}$ ($A_2, A_3 > 0 \Rightarrow A_4 < 0$) as in figure 2(b),
- converge in both directions $e_{(2)}, e_{(3)}$ ($A_2, A_3 < 0 \Rightarrow A_4 > 0$) as in figure 3(d),
- recede in one direction and converge in the other, but not by the same amount ($A_2, A_3$ have opposite signs, $|A_2| \neq |A_3| \Rightarrow A_4 \neq 0$) as in figures 2(c), 2(d) or figures 3(b), 3(c),
- behave as in the standard $D = 4$ general relativity ($A_3 = -A_2 \Rightarrow A_4 = 0$) as in figure 4(c), that is

$$-\Psi_{4ij}^{\text{nat}} = \begin{pmatrix} A_2 & 0 & 0 & 0 \\ 0 & -A_2 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$  

- $A_3 = 0$ or $A_2 = 0$, so that

$$-\Psi_{4ij}^{\text{nat}} = \begin{pmatrix} A_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -A_2 & 0 \end{pmatrix} \quad \text{or} \quad -\Psi_{4ij}^{\text{nat}} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & A_3 & 0 & 0 \\ 0 & 0 & 0 & -A_3 \end{pmatrix}.$$  

We can distinguish two subcases of this anomalous behaviour, namely
Using the conditions summarized in the first four rows of table 3, expressions (29)–(32) there is also an additional kinematic effect for non-static observers with non-vanishing velocity in the transverse space, ∂x^p \propto \Psi_{ij}^{nat}, \Psi_{3ij}^{nat}, \Psi_{2ij}^{nat}, \Psi_{2ij}^{nat} = 0. The equations of geodesic deviation (57), (58) thus become

\[
\dot{Z}^{(1)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(1)} - \dot{\Psi}_{3ij}^{nat} Z^{(j)},
\]

\[
\dot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} - \dot{\Psi}_{ij}^{nat} Z^{(j)} - 2 \dot{u} \dot{x}^p g_{pq} (\Psi_{3ij}^{nat}, m^q j) Z^{(j)}. \tag{76}
\]

Using the conditions summarized in the first four rows of table 3, expressions (29)–(32) for the non-trivial Weyl scalars Ψ_{ij}^{nat}, Ψ_{3ij}^{nat}, Ψ_{2ij}^{nat} reduce to

\[
\Psi_{3ij}^{nat} = -m^p D - 3 \left[ \left( a_p + f_p a \right) r + \frac{1}{2} \left( b_p - f_p u \right) - \frac{2 c_p}{D-2} \left( \frac{SR}{D-3} + f \right) + \frac{1}{2} f^q e_q f_p - \frac{2}{D-3} E^{pq} - \frac{\dot{u} x^p g_{pq}}{D-2} \right],
\]

\[
\Psi_{ij}^{nat} = \Psi_{2ij}^{nat} + \frac{1}{D-3} (\delta_{ij} \Psi_{3ij}^{nat} - \delta_{jk} \Psi_{3jk}^{nat}), \tag{77}
\]

\[
\Psi_{2ij}^{nat} = m^p m^q m^r (X_{pqm} = \frac{1}{D-3} (g_{pm} X_q - g_{pq} X_m)),
\]

\[
\Psi_{4ij}^{nat} = m^p m^q (W_{pq} = \frac{1}{D-2} g_{pq} W),
\]

where \( a = \frac{1}{4} f^p f_p - \frac{1}{D-2} \left( \frac{SR}{D-3} + f \right), \quad X_q \equiv g^{pq} X_{pqm}, \quad W \equiv g^{pq} W_{pq} \) and

\[
X_{pqm} = e_{[q][m]|p|u} - e_{p[m]f_q} - f_{p[m]e_q} + g_{p[m,u]|q}.,
\]

\[
W_{pq} = -\frac{r}{2} \left[ \frac{1}{2} a^q |p|q + \frac{1}{2} a^q |q|p + \frac{1}{2} a^q |p|q + \frac{1}{2} a^q |q|p \right]
\]

\[-\frac{1}{4} b^q |p|q + \frac{1}{2} c^q |p|q + \frac{1}{2} c^q |q|p - \frac{1}{2} e^q |p|q + \frac{1}{2} e^q |q|p - \frac{1}{2} b_{pq} - b_{(p|q)} + 2a^q f_{(p|q)} - 2a^q f_{(q|p)} - f_{(p|q,u)} - f_{(p,u|q)}
\]

\[+ c_{(p|q,u)} + c_{(p,u|q)} - \frac{1}{2} g_{pq,uu} + g^{mn} E_{mp} E_{pq} + f^m E_{mp} e_q + e^m E_{mp} f_q - \frac{1}{2} c^m e_m f_p f_q + f^m f_m e_f e_q - \frac{1}{2} f^m e_m f_p f_q .
\]

In addition to the isotropic influence of the cosmological constant Λ and the transverse effects of gravitational waves described by Ψ_{ij}^{nat} (which are typical for type O and N spacetimes, respectively), type III Kundt spacetimes feature a longitudinal effect proportional to the scalars Ψ_{3ij}^{nat}, see (75). Moreover, from (76) we conclude that there is also an additional kinematic effect for non-static observers — those with a non-vanishing velocity in the transverse space, \dot{x}^p \neq 0. Measuring relative motions
between geodesic observers with non-trivial spatial velocities we can thus determine other components of the curvature tensor, namely the symmetric part of $\Psi_{3(i)k}$.

If, and only if, $\Psi_{4ij} = 0$, the geometry is of algebraic type III, with respect to the triple WAND $k^{\text{nat}}$ and WAND $l^{\text{nat}}$.

5.4. Subtype III(a)

For the subtype III(a) of Kundt spacetimes, there is $\Psi_{3Tj}^{\text{nat}} = 0$, see table 3 and [9]. The equations of geodesic deviation (75), (76) thus simplify to

$$\ddot{Z}^{(1)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(1)} - \dot{u} \Psi_{3Tj}^{\text{nat}} Z^{(j)},$$

$$\ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} - \dot{u} \tilde{\Psi}_{3(i)j}^{\text{nat}} Z^{(j)} + 2 \dot{u} \dot{x}^p g_{pq} \tilde{\Psi}_{3(i)k}^{\text{nat}} m^k q^i Z^{(j)}.$$  (80)

Apart from the cosmological background $A$-term, there are only transverse effects given by the scalars $\Psi_{3Tj}^{\text{nat}}$ and $\Psi_{3(i)j}^{\text{nat}}$. The latter contribution is purely kinematical, i.e., it is absent for $\dot{x}^p = 0$. For such static observers, the geodesic deviation is the same as for type N spacetimes, cf. (63), (64). The specific contributions of $\tilde{\Psi}_{3(i)j}^{\text{nat}}$ can be identified by considering non-static observers with mutual velocities $\dot{x}^p \neq 0$.

5.5. Subtype III(b)

For the subtype III(b) of Kundt spacetimes, there is $\tilde{\Psi}_{3(i)j}^{\text{nat}} = 0$, see table 3 and [9]. In such a case, the equations (75), (76) become

$$\ddot{Z}^{(1)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(1)} - \dot{u} \Psi_{3Tj}^{\text{nat}} Z^{(j)},$$

$$\ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} - \dot{u} \Psi_{3Tj}^{\text{nat}} Z^{(j)} - \dot{u}^2 \Psi_{4ij}^{\text{nat}} Z^{(j)} - 2 \frac{D-2}{D-3} \dot{u} \dot{x}^p g_{pq} \left( \Psi_{3T(m)}^{\text{nat}} m^q_j - \frac{\delta_{ij}}{D-2} \Psi_{3Tn}^{\text{nat}} m^k q^i \right) Z^{(j)}.$$  (82)

The geodesic deviation is thus fully determined by the scalars $\Lambda$, $\Psi_{3Tj}^{\text{nat}}$ and $\Psi_{4ij}^{\text{nat}}$ via the corresponding isotropic, transverse and longitudinal effects, respectively. For observers with non-vanishing spatial velocities $\dot{x}^p \neq 0$, transverse motion is modified by the presence of $\Psi_{3Tj}^{\text{nat}}$. This additional effect is traceless since $\delta^{ij} \Psi_{3T(m)}^{\text{nat}} m^q_j = \Psi_{3Tn}^{\text{nat}} m^m q^i$.

5.6. Type D Kundt spacetimes

For type D Kundt spacetimes (22) with a double WAND $k^{\text{nat}} = k = \partial_x$ and a double WAND $l^{\text{nat}} = \frac{1}{2} g_{nu} \partial_r + \partial_\nu$, all the Weyl scalars $\Psi_{A}^{\text{nat}}$ vanish, except for the boost weight 0. Therefore, the equations of geodesic deviation are (57), (58) with

$$\Psi_{2S} = \Psi_{2S}^{\text{nat}}, \quad \Psi_{2T(i)} = \Psi_{2T(i)}^{\text{nat}},$$

$$\Psi_{3T} = \sqrt{2} \dot{x}^p g_{pq} \left( \Psi_{2T(m)}^{\text{nat}} - \Psi_{2T(m)}^{\text{nat}} m^q_j - \Psi_{2S}^{\text{nat}} m^q_j \right),$$

$$\Psi_{4ij} = 2 \dot{x}^p g_{pq} \left( g_{pq} \Psi_{2T(m)}^{\text{nat}} + g_{pm} g_{qn} \Psi_{2S}^{\text{nat}} m^m_i j^m + g_{pm} g_{qn} \Psi_{2S}^{\text{nat}} m^k m^l_j \right) - 2 g_{pm} g_{qn} \left( \Psi_{2S}^{\text{nat}} + \Psi_{2S}^{\text{nat}} m^k m^l_j \right).$$  (83)

where $\Psi_{2S}^{\text{nat}}$, $\Psi_{2T(i)}^{\text{nat}}$, $\Psi_{2T(m)}^{\text{nat}}$, $\Psi_{2S}^{\text{nat}}$, are explicitly given by expressions (23)–(28).
Interestingly, in higher dimensions, the local behaviour of test particles in subtype D(a) tonian deformations (88) are traceless since $\delta^{(25)}$. There is no longitudinal Newtonian motion spacetimes, as given by expressions (87), (88), is very similar to the effect caused by

The subtype D(b) occurs if, and only if, $\tilde{\Psi}^{5.8. Subtype D(a)}$

The subtype D(a) is defined by the condition

This is equivalent to $g_{uu} = a r^2 + b r + c$ where $a = \frac{1}{2} f^p f_p - \frac{1}{2} \left( \frac{\tilde{\Psi}^p}{g^{pp}} + f \right)$, cf. (23) and the first row in table 3. The geodesic deviation equations (84), (85) reduce to

where, in view of (24), (86), we have $\Psi_{2S}^{nat} = \tilde{\Psi}_{2T}^{nat}$ which is explicitly expressed by (25). There is no longitudinal Newtonian motion, see (87), and the transverse Newtonian deformations (88) are traceless since $\delta^{(j)} \Psi_{2T}^{nat} = \Psi_{2T}^{nat} = \Psi_{2S}^{nat} = 0$, see (6). Interestingly, in higher dimensions, the local behaviour of test particles in subtype D(a) spacetimes, as given by expressions (87), (88), is very similar to the effect caused by type N gravitational waves (63), (64). Due to this close formal similarity, we can use figures 2–4 to illustrate particle motion in the $D = 5$ case. Such a situation does not appear in the $D = 4$ case since $\Psi_{2T}^{nat} = \Psi_{2T}^{nat} = 0$, as we can see from (25).

For geodesics with spatial velocities $\dot{x}^p \neq 0$, there are additional terms $\Psi_{2T}^{nat}, \Psi_{44}$, given by (57), (58), (83). The scalars $\Psi_{2T}^{nat}, \Psi_{2T}^{nat}, \Psi_{2T}^{nat}$ take the form (28) and (26), (27).

5.8. Subtype D(b)

The subtype D(b) occurs if, and only if, $\tilde{\Psi}_{2T}^{nat} = 0$. From (24) it thus follows that

Due to (25), this is equivalent to $SR_{pq} = \frac{1}{D-2} g_{pq} SR = -\frac{1}{2} (D-4) (f_{pq} - \frac{1}{D-2} g_{pq} f)$, see [9] and the second row in table 3. For such Kundt geometries, the equations of geodesic deviation (84), (85) take the form

We can see that the Newtonian part of the gravitational field is now fully determined by a single scalar $\Psi_{2S}^{nat}$ given by (23). Moreover, motion in the transverse spatial directions $i, j = 2, \ldots, D - 1$ is isotropic (its sum is fully offset to zero by the longitudinal motion, $\delta^{ij} \Psi_{2T}^{nat} = \Psi_{2S}^{nat}$). A sphere of test particles, initially at
rest, is thus deformed into a rotational ellipsoid with the axis $e_{(1)}$, see figure 5. Interestingly, this type of behaviour enables us to determine experimentally the dimension $D$ of the spacetime. Subtracting the isotropic motion given by $\Lambda$, it is possible to measure the relative acceleration in the longitudinal direction $e_{(1)}$ and compare it with the acceleration in any transverse direction $e_{(2)}$, say, obtaining
\[
\frac{\ddot{Z}^{(1)}}{Z^{(1)}} = 2\Lambda \left(\frac{D-2}{2(D-1)}\right) Z^{(1)} - \frac{1}{\sqrt{2}} \Psi_{3T}^{ij} Z^{(j)},
\]
\[
\frac{\ddot{Z}^{(2)}}{Z^{(2)}} = 2\Lambda \left(\frac{D-2}{2(D-1)}\right) Z^{(1)} - \frac{1}{\sqrt{2}} \Psi_{4ij}^{(2)} Z^{(j)},
\]
where (83) becomes
\[
\Psi_{3T}^{ij} = 3 \sqrt{2} m^{p} F_{pq} \dot{x}^{q}, \quad \Psi_{4ij}^{(2)} = 2 m^{m} m^{n} \left(\delta_{mpq} - 3F_{p(m} g_{n)q}\right) \dot{x}^{p} \dot{x}^{q}.
\]
Interestingly, for static observers ($\dot{x}^{p} = 0$), we have $\Psi_{3T}^{ij} = 0 = \Psi_{4ij}^{(2)}$ and the equations contain only the cosmological constant $\Lambda$-term. The relative motion of such test particles is the same as in the type $O$ spacetimes (61) — it is fully isotropic as in the background Minkowski, de Sitter or anti-de Sitter spaces.

Recall also that in the classic $D = 4$ case, the subtypes $D(ab)$ and $D(a)$ are identical because the condition for the subtype $D(b)$ is always satisfied [9].

5.10. Subtype $D(c)$

The algebraic subtype $D(c)$ is defined by the condition $\Psi_{2S}^{nat} = 0$ which, using (27), is equivalent to $\delta_{mpq} = 0$, cf. the third row in table 3. Since $\Psi_{2S}^{nat}$ and $\Psi_{2T}^{nat}(ij)$ are

\[\text{Figure 5. Deformation of a sphere of static test particles in the subtype D(b) when } D = 5 \text{ for the cases (a) } \Psi_{2S}^{nat} < 0, \text{ (b) } \Psi_{2S}^{nat} > 0. \text{ Unlike in figures 2–4, here we show } e_{(1)}, e_{(2)}, e_{(3)} \text{, where } e_{(1)} \text{ is the longitudinal direction (oriented horizontally) while } e_{(2)}, e_{(3)} \text{ (plotted perpendicularly) are two directions of the transverse 3-space (the third equivalent transverse direction } e_{(4)} \text{ is suppressed).} \]
generally non-vanishing, this subtype of the Kundt geometries cannot be distinguished by measuring the deviation (84), (85) of static geodesic observers. In principle, it can be detected in the relative motion of non-static particles with \( \dot{x}^p \neq 0 \) as the \( \Psi_{4T,j}^{nat} \) component in the amplitude \( \Psi_{4T;j} \) determined by (83) is absent.

Moreover, as discussed in [9], the condition for subtype D(c) is identically satisfied in the cases \( D = 4 \) and \( D = 5 \).

5.11. Subtype D(d)

The subtype D(d) occurs if, and only if, \( \Psi_{4T,j}^{nat} = 0 \). In view of (28), this is equivalent to \( F_{pq} = 0 \) (see table 3). As in the subcase D(c), this is not directly observable in the geodesic deviation (84), (85) of static observers, but it is implied by the absence of the \( \Psi_{4T;j}^{nat} \) component entering the scalars \( \Psi_{3T}, \Psi_{4T;j} \) via (83). It is detectable by observers with \( \dot{x}^p \neq 0 \) for which the equations of geodesic deviation take the form (57), (58).

5.12. Type II Kundt spacetimes

The general form of the geodesic deviation equations for any Kundt spacetime (22) of algebraic type II (or more special) with (at least) a double WAND is

\[
\ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} + \Psi_{2S}^{nat} Z^{(i)}
\]

\[
- \left[ \ddot{\Psi}_{2T;j}^{nat} + \dot{x}^p g_{pq} \left( \frac{3}{2} \Psi_{2T;j}^{nat} m^q - \Psi_{2T;j}^{nat} m^q \right) - \frac{D-1}{D-2} \Psi_{2S}^{nat} m^q \right] Z^{(j)},
\]

\[
\ddot{Z}^{(i)} = \frac{2\Lambda}{(D-2)(D-1)} Z^{(i)} - \left( \ddot{\Psi}_{2T;j}^{nat} + \frac{\delta_{ij}}{D-2} \Psi_{2S}^{nat} \right) Z^{(j)} - \dot{\Psi}_{4T;j}^{nat} Z^{(j)}
\]

\[
- 2\dot{\Psi}_{2T;j}^{nat} \left( \frac{D-2}{D-3} \Psi_{2T;j}^{nat} - \frac{\delta_{ij}}{D-3} \Psi_{4T;j}^{nat} m^q \right) - \frac{D-1}{D-2} \Psi_{2S}^{nat} m^q \right] Z^{(j)}
\]

\[
- \dot{\dot{\Psi}}_{2T;j}^{nat} \left[ \frac{g_{mp}m^p m^q}{D-4} \left( 2\delta_{ij} \Psi_{2T;j}^{nat} + \Psi_{2T;j}^{nat} m^q \right) - \frac{D-1}{D-2} \Psi_{2S}^{nat} m^q \right] Z^{(j)}.
\]

The behaviour of test particles in the subtypes II(a), II(b), II(c) and II(d) is easily obtained by setting \( \Psi_{2S}^{nat} = 0, \dot{\Psi}_{2T;j}^{nat} = 0, \ddot{\Psi}_{2T;j}^{nat} = 0 \) and \( \Psi_{4T;j}^{nat} = 0 \), respectively.

When all these Weyl scalars of the boost weight 0 vanish, we obtain the type III Kundt geometries with a triple WAND \( k \) and recover the results of sections 5.3–5.5. If, in addition, \( \Psi_{4T;j}^{nat} = 0 \), the spacetimes are of type N with a quadruple WAND \( k \) as discussed in 5.2, and with \( \Psi_{4T;j}^{nat} = 0 \) they become type O, see 5.1. Alternatively, if only \( \Psi_{4T;j}^{nat} = 0 \), given by (32), (35), (36), the spacetime is of algebraic type II, with respect to a double WAND \( k^{nat} = \partial_r \) and WAND \( l^{nat} = \frac{1}{2} g_{au} \partial_r + \partial_u \). When only the scalars \( \Psi_{4T;ij}^{nat}, \Psi_{3T;3}^{nat} \) are non-trivial, the geometry is of algebraic type III, with respect to a triple WAND \( k^{nat} \) and WAND \( l^{nat} \).

Type D Kundt geometries of section 5.6 arise by setting \( \Psi_{4T;j}^{nat} = 0 = \ddot{\Psi}_{2T;j}^{nat} \) and \( \dot{\Psi}_{4T;j}^{nat} = 0 \), in which case the expressions (95), (96) correspond to (83). The subtypes
D(a), D(b), D(c) and D(d) are obtained when $\Psi^{2S}_{\text{nat}} = 0$, $\Psi^{2T(i)}_{\text{nat}} = 0$, $\Psi^{2T(\epsilon,\eta)}_{\text{nat}} = 0$ and $\Psi^{2\epsilon}_{\text{nat}} = 0$, respectively, reducing the results to those discussed in sections 5.7–5.11.

6. Example: type II and N gravitational waves on D and O backgrounds

As an interesting illustration, we can consider a line element of the form
\[ ds^2 = g_{pq} \, dx^p dx^q - 2 \, du \, dr + (a \, r^2 + c) \, du^2, \]
where $g_{pq} = g_{pq}(x)$, $a = \text{const.}$ and $c = c(u, x)$.

The possible algebraic structure of such Kundt geometries is summarized in table 4.

Table 4. The structure of all Kundt geometries (97) with respect to a multiple WAND $k^{\alpha\beta} = \partial_{\alpha}$ and (possibly double) WAND $l^{\alpha\beta} = \frac{1}{2} (a \, r^2 + c) \partial_{\alpha} + \partial_{\beta}$.

The relative motion of free test particles in these spacetimes is described by equations (57), (58) where the scalars (59) take the form
\[
\begin{align*}
\Psi^{2S}_{\text{nat}} &= \frac{D-3}{D-1} \left( a + \frac{S^R}{(D-2)(D-3)} \right), \\
\Psi^{2T(i)}_{\text{nat}} &= \frac{m^p_i m^q_j}{D-2} \left( S^R_{pq} - \frac{g_{pq}}{D-2} \, S^R \right) + \delta_{ij} \frac{D-3}{D-2} \left( a + \frac{S^R}{(D-2)(D-3)} \right), \\
\Psi^{3T}_{\text{nat}} &= -\frac{\sqrt{2}}{D-2} \, x^p m^q_j \left( S^R_{pq} + (D-3) \, a \, g_{pq} \right), \\
\Psi^{4T}_{\text{nat}} &= -\dot{u}^2 m^p_i m^q_j \left( c_{|[\cdot]|[\cdot]} - \frac{g_{pq}}{D-2} \, \triangle c \right) \\
&\quad + 2 \, \dot{x}^p \, x^q m^m_i m^n_j \left( S^C_{mpnq} + \left( a + \frac{S^R}{(D-2)(D-3)} \right) \left( \frac{g_{pq} g_{mn}}{D-2} - g_{pm} g_{qn} \right) \right) \\
&\quad + \frac{1}{D-4} \left[ g_{pq} \left( S^R_{mn} - \frac{g_{mn}}{D-2} \, S^R \right) + \frac{2 \, g_{mn}}{D-2} \left( S^R_{pq} - \frac{g_{pq}}{D-2} \, S^R \right) - g_{pm} \left( S^R_{qn} - \frac{g_{qn}}{D-2} \, S^R \right) - g_{qn} \left( S^R_{pm} - \frac{g_{pm}}{D-2} \, S^R \right) \right].
\end{align*}
\]
Notice that for the subtype $\Pi(ab)\equiv \Pi(abd)$, this simplifies considerably to
\[
\begin{align*}
\dot{z}^{(1)} &= \frac{2\Lambda}{(D-2)(D-1)} z^{(1)}, \\
\dot{z}^{(i)} &= \frac{2\Lambda}{(D-2)(D-1)} z^{(i)} + \frac{1}{2} \dot{u}^2 m_i^p m_j^n \left( c_{[p][q]} - \frac{g_{pq}}{D-2} \Delta \epsilon \right) Z^{(j)} \\
&\quad - \dot{x}^p \dot{x}^q m_i^p m_j^n \tilde{S}_{mpnq} Z^{(j)} .
\end{align*}
\]
When, in addition, $\tilde{S}_{mpnq} = 0$, this becomes type $\Pi(abcd)\equiv N$.

If, and only if, $c_{[p][q]} = \frac{1}{D-2} g_{pq} \Delta \epsilon$, the spacetimes are of type D or type O. When $c = 0$, these belong to the important family of direct-product spacetimes, see section 11 of [9], for which the first term of the metric (97) is a $(D-2)$-dimensional Riemannian space with metric $g_{pq}(x)$, while the second part is a 2-dimensional Lorentzian spacetime of constant Gaussian curvature $a$. In general, $g_{pq}(x)$ need not be of constant curvature, but for the subtype $D(a)$, $a$ is uniquely related to the constant Ricci scalar $\tilde{S} \tilde{R}$ of the transverse $(D-2)$-dimensional space. Such metrics represent natural higher-dimensional generalizations of the (anti-)Nariai, Plebański–Hacyan, Bertotti–Robinson and Minkowski spacetimes of types D or O, see [4].

For a non-trivial $c$, the spacetimes (97) are of type II or of type N. These can be naturally interpreted as the class of exact Kundt gravitational waves with the profile $c(u, x)$ propagating in various direct-product background universes of algebraic types D or O mentioned above (and listed in table 6 of [9]; see also [23, 24, 43]).

The class of metrics (97) clearly contains $pp$-waves (without gyratonic sources) propagating in flat space when $a = 0$. These are of type N if, and only if, $g_{pq} = \delta_{pq}$ (in which case they belong to the class of VSI spacetimes, see [9]).

Finally, let us observe that in the classic $D = 4$ case, the scalars (99) read
\[
\begin{align*}
\Psi_{2S} &= \frac{1}{3} \left( a + \frac{1}{2} \tilde{S} \tilde{R} \right) , \\
\Psi_{2T^{(ij)}} &= \frac{1}{6} \delta_{ij} \left( a + \frac{1}{2} \tilde{S} \tilde{R} \right) , \\
\Psi_{3T^{ij}} &= -\frac{\sqrt{2}}{2} \dot{x}^p m_i^p \left( \tilde{S} R_{pq} + a g_{pq} \right) , \\
\Psi_{4T^{ij}} &= -\dot{u}^2 m_i^p m_j^n \left( c_{[p][q]} - \frac{1}{2} g_{pq} \Delta \epsilon \right) + \dot{x}^p \dot{x}^q m_i^p m_j^n \left( a + \frac{1}{2} \tilde{S} \tilde{R} \right) \left( g_{pq} g_{mn} - 2 g_{pm} g_{qn} \right) .
\end{align*}
\]
The corresponding Kundt geometries (97) are thus generally of type $\Pi(abc)$. They are of type $N$ if $D(a) (abcd)$ if, and only if, $a = -\frac{1}{2} \tilde{S} \tilde{R}$ with the only non-vanishing Weyl scalar $\Psi_{4T} = -\dot{u}^2 m_i^p m_j^n \left( c_{[p][q]} - \frac{1}{2} g_{pq} \Delta \epsilon \right)$. In fact, this is the subfamily $\alpha = \beta, \epsilon = 1, C = 0$ of spacetimes discussed in [43] and in sections 18.6–18.7 of [4] (with the identification $\alpha = \beta = \frac{1}{2} \tilde{S} \tilde{R}$, $D = a$ and $H = -c$) which was interpreted as exact Kundt gravitational waves of type II propagating on type D backgrounds, and type N waves propagating on conformally flat type O backgrounds, respectively. These background universes with the geometry of a direct product of two constant-curvature 2-spaces involve the standard Minkowski, Bertotti–Robinson, (anti-)Nariai and Plebański–Hacyan spacetimes, cf. [23, 58, 59].

7. Conclusions
We have systematically analyzed the general class of Kundt geometries in an arbitrary dimension $D \geq 4$ using the geodesic deviation in Einstein’s theory. We have explicitly determined the specific motion of free test particles for all possible algebraically special spacetimes, including the corresponding subtypes, and demonstrated that the
invariant quantities determining these (sub)types are measurable by detectors via characteristic relative accelerations. For example, the dimension of the spacetime can be measured directly by Newtonian-type tidal deformations of the algebraic subtype D(b). The purely transverse type N effects represent exact gravitational waves with \(D(D - 3)/2\) polarizations, which exhibit new and peculiar observable effects in higher dimensions \(D > 4\). We have given an example of such geometric and physical interpretation of the Kundt family by analyzing the class of type N or II gravitational waves propagating on backgrounds of type O or D.
